FLORIDA POULTRY SUMMARY

Commercial Flocks

Florida laying flocks are becoming more commercialized. Number of farms with layers are declining while total layers in the state are on the increase. On November 1, 1962, there were 5,161,000 layers in commercial flocks (farms with 400 or more layers) in Florida. This was an increase of nearly 13 percent over a year earlier and 23 percent above the number on November 1, 1960. These layers were held by 824 commercial poultrymen with an average of 6,263 birds per flock. This compares with 4,578 layers held by 859 poultrymen with an average of 5,329 birds per flock on November 1, 1961. On November 1, 1960, there were 1,037 commercial flocks with an average of 4,052 per flock.

On November 1, 1962, commercial egg flocks and breeder flocks for supplying hatching eggs constituted about 93 percent of all layers in Florida. Of the 5,161,000 in commercial flocks 51.3 percent were hens over 1 year old, compared with 47.8 a year earlier. At the same time, producers were carrying enough replacement pullets over 3 months old to replace 18.0 percent of their flock, compared with 19.2 percent in 1961. Total birds of all ages in commercial flocks November 1, 1962, at 6,522,000 compares with 5,987,000, November 1, 1961.

All Laying Flocks

In order to show a distribution of the total chicken population in Florida, the state was divided into five marketing areas based largely on centers of population and surrounding areas. The current monthly estimates of layers in the State published by the Florida Crop and Livestock Service include layers in all flocks--commercial flocks (farms with 400 or more layers), breeder flocks (layers in flocks supplying hatching eggs), and non-commercial flocks (farms with less than 400 layers). On November 1, 1962, there were 5,867,000 layers in "all" flocks in Florida, up 8 percent from a year earlier.

This report is intended to provide basic information to poultry and egg producers, shippers, processors and marketing agencies as a guide in production and marketing plans for the rapidly changing poultry industry in Florida. In addition to providing information for the poultry industry, statistics from these surveys are used as a bench mark in making monthly estimates of layers and egg production.

Composition of Commercial Flocks

Total birds in commercial flocks on November 1, 1962, was 6,522,000, 9 percent above the number on November 1, 1961. Increases occurred in all areas of the State with the exception of area III which was down only slightly. This resulted from a decline in replacement birds as layers increased. Area II registered the greatest increase over a year earlier. Birds of laying age on November 1, 1962, were greater than a year earlier in all areas of the State. Layers over one year old accounted for a greater percentage of the laying flock in Areas II, III, and V, or North East, West Central, and Lower East Coast Areas. Pullets 3 months to laying age available for flock replacements were up from a year earlier only in Area IV. The number of birds under 3 months old as percentage of layers (primarily young pullets) registered a decline in all areas of the State.

Layers in commercial flocks account for about 87 percent of total layers in Florida. When breeding flocks are considered, percentage of total is 93 percent and only 7 percent for farm flocks.

Number of Farms by Size Groups and Areas

Commercial egg farms in Florida totaled 824 on November 1, 1962. Of this number, 14.7 percent were in Area I, 13.4 percent in Area II, 46.5 percent in Area III, 13.7 percent in Area IV, and 11.7 percent in Area V. The number of commercial flocks in the 9500 and over group registered an increase over the previous year in all areas of the State. Number of farms in the small size group, 400-1499 declined in all areas. The average number of layers per farm was largest in Area II with 10,198, Area V was second with 6,396. In Area IV the average was 6,345, Area III 5,728, and Area I averaged 4,165. All areas registered an increase in layers per farm over the previous year.

Survey Procedure

An inquiry was mailed to all known commercial egg producers in Florida. Non-respondents to this inquiry were mailed a second or third questionnaire. Four hundred thirty reports were obtained by mail, leaving 394 poultrymen who had not replied. These respondents were stratified by size of operation. A sample of 204 farms were selected and enumerated by personal contact. Reports were obtained from all producers with 4,500 or more birds. Replies by mail plus enumerated producers totaled 89 percent of the estimated layers in commercial flocks.

Florida Layers and Egg Production

The Florida Crop and Livestock Reporting Service has prepared these estimates for Florida's more important egg producing counties in response to numerous requests for this type of information. These data were developed primarily from an enumeration of major commercial producers in these counties, and the 1959 Census of Agriculture in "other" counties. The less important counties have not been listed individually because it was not possible to enumerate a sufficient number of producers in them to obtain reliable county by county figures for 1961.

The number of layers shown is the estimated average number for the county for the year. The number of producing birds in flocks varies significantly during the year in Florida.

Most of the data used in this report was obtained in the 1961 survey of Florida's commercial egg flocks--a project in which the Poultry and Egg Section and the State Marketing Bureau of the Florida Department of Agriculture cooperated with this Service.
